

## CSS 342 Big-oh Practice Problems Solution

\*\*\* These solutions are for your personal use only. \*\*\*

Note -- best to print these using some non-proportional font, like courier new,  
(for correct formatting)  
-- the character ^ is used for exponentiation here (it isn't in C++)

1. Consider the definition:

$T(n) = O(f(n))$  if there exists constants  $n_0$  and  $c > 0$   
so that  $T(n) \leq c \cdot f(n)$  for all integers  $n > n_0$ .

Find values for  $n_0$  and  $c$  to prove the following are big-oh relationships.

(a). Prove  $2^{(n+10)}$  is  $O(2^n)$

$2^{(n+10)} = 2^{10} * 2^n$  add exponents when you multiply

So let  $n_0 = 1$  and  $c = 2^{10}$ .

Then  $2^{(n+10)} \leq 2^{10} * 2^n$  for all  $n > 1$ .

(b). Prove  $n^{10}$  is  $O(3^n)$

This one is easier to see with experimentation.  $3^n$  is an exponential function which eventually grows very fast while  $n^{10}$  is a polynomial, a polynomial with a large power, but still a polynomial. The question is when does  $3^n$  surpass  $n^{10}$ ? I wrote a simple program comparing  $3^n$  to  $n^{10}$ . Here is the output showing when  $3^n$  surpasses  $n^{10}$ . You can see once  $3^n$  starts growing, passing  $n^{10}$ , it grows big very fast. (Output is from using an 8-byte long int.)

$n = 30$	$n^{10} =$	590490000000000
	$3^n =$	205891132094649

$n = 31$	$n^{10} =$	819628286980801
	$3^n =$	617673396283947

$n = 32$	$n^{10} =$	1125899906842624
	$3^n =$	1853020188851841

$n = 33$	$n^{10} =$	1531578985264449
	$3^n =$	5559060566555523

$n = 34$	$n^{10} =$	2064377754059776
	$3^n =$	16677181699666569

$n = 35$	$n^{10} =$	2758547353515625
	$3^n =$	50031545098999707

So let  $n_0 = 32$  and  $c = 1$ . Then  $n^{10} \leq 1 \cdot 3^n$  for all  $n \geq 32$ .

This is the way to attack it if you want  $c = 1$ . An alternative arithmetic approach is to choose  $n_0$  and figure out what  $c$  must be.

(c). Prove that  $O(n) + O(n) = O(n)$ .

Let  $T_1(n) = O(n)$ . Then there exists positive constants  $c_1, n_1$  such that  $T_1(n) \leq c_1 * n$  for all  $n > n_1$ .

Let  $T_2(n) = O(n)$ . Then there exists positive constants  $c_2, n_2$  such that  $T_2(n) \leq c_2 * n$  for all  $n > n_2$ .

To show  $O(n) + O(n) = O(n)$ , we must show there exists positive constants  $c, n_0$  such that  $T_1(n) + T_2(n) \leq c * n$  for all  $n > n_0$ .

By above,  $T_1(n) + T_2(n) \leq c_1 \cdot n + c_2 \cdot n$  for all  $n > \max(n_1, n_2)$ .

So let  $c = c_1 + c_2$  and  $n_0 = \max(n_1, n_2)$ .

Then  $T_1(n) + T_2(n) \leq c_1 \cdot n + c_2 \cdot n$  for all  $n > n_0$   
 $\leq (c_1 + c_2) \cdot n$   
 $\leq c \cdot n$

Thus,  $T_1(n) + T_2(n) = O(n) + O(n) = O(n)$ .

2. Give a big-oh upper bound on the running time of the trivial selection statement

```
if (C) { }
```

where  $C$  is a condition that does not involve any function calls.

Whether the condition  $C$  is true or false, the running time of the if is  $O(1)$ .

3. Repeat the last problem for the trivial while-loop
- ```
while (C) { }
```

If the condition  $C$  is false, the running time of the while-loop is  $O(1)$ .

If the condition is true, the while-loop executes forever and the running time is not defined.

4. Give a rule for the running time of a selection statement in which we can tell which branch is taken, such as

```
if (1 == 2)
    something O(f(n));
else
    something O(g(n));
```

In this case, the running time is  $O(g(n))$ . In general, the running time is that of the branch taken.

5. Give a rule for the running time of a degenerate while-loop, in which the condition is known to be false right from the start, such as

```
while (1 != 1)
    something O(f(n));
```

If the condition  $C$  is known to be false, the running time is  $O(1)$ , the constant time to evaluate the condition.

6. Give an analysis of the running time (find tight big-oh) of a function which finds the average of the elements of an array  $A[0..n-1]$ .

$$T(n) = O\left(1 + \sum_{i=0}^{n-1} 1\right) = O\left(1 + \sum_{i=1}^n 1\right) = O(1+n).$$

for initialization before loop and arithmetic after loop

Thus the running time of the entire program is  $O(n)$ .

7. The following is a program fragment that applies the powers-of-2 operation to the integers  $i$  from 1 to  $n$ . Give a tight big-oh upper bound of the

running time. A discussion is sufficient proof of complexity.

```
for (i = 1; i <= n; i++) {
    m = 0;
    j = n;
    while (j > 0) {
        j /= 2;
        m++;
    }
}
```

The assignment statements each take  $O(1)$  time. The running time of the while-loop is  $O(\log n)$  because the value of  $j$  is cut in half each time through the loop. Since the while loop is nested in the for loop,  $\log n$  execution steps happens each time through the loop. Thus the running time of the for loop is  $O(n \log n)$ .

8. Give an analysis of the running time (find tight big-oh) for the following segments of code.

(a). 

```
for (sum = 0, int i = 1; i <= n; i++)
    for (int j = 1; j <= n*n; j++)
        sum++;
```

$$\begin{array}{c} n \\ \text{---} \\ \backslash \\ / \end{array} \begin{array}{c} n^2 \\ \text{---} \\ \backslash \\ / \end{array} 1 = \begin{array}{c} n \\ \text{---} \\ \backslash \\ / \end{array} n^2 = n^3 \quad \text{So } T(n) = O(n^3)$$

$i=1 \quad j=1 \quad i=1$

(b). 

```
for (sum = 0, int i = 1; i <= n; i++)
    for (int j = 1; j <= i; j++)
        sum++;
```

$$\begin{array}{c} n \\ \text{---} \\ \backslash \\ / \end{array} \begin{array}{c} i \\ \text{---} \\ \backslash \\ / \end{array} 1 = \begin{array}{c} n \\ \text{---} \\ \backslash \\ / \end{array} i = \frac{n(n+1)}{2} \quad \text{So } T(n) = O(n^2)$$

$i=1 \quad j=1 \quad i=1$

(c). 

```
for (int i = 0; i < n; i++)
    sum++;
for (int i = 0; i < n; i++)
    sum++;
```

$$\begin{array}{c} n-1 \\ \text{---} \\ \backslash \\ / \end{array} 1 + \begin{array}{c} n-1 \\ \text{---} \\ \backslash \\ / \end{array} 1 = \begin{array}{c} n \\ \text{---} \\ \backslash \\ / \end{array} 1 + \begin{array}{c} n \\ \text{---} \\ \backslash \\ / \end{array} 1 = n + n = 2n \quad \text{So } T(n) = O(n)$$

$i=0 \quad i=0 \quad i=1 \quad i=1$

(d). 

```
for (sum = 0, int i = 1; i <= n; i++)
    for (int j = 1; j <= i*i; j++)
        if (j % i == 0)
            for (int k = 1; k <= j; k++)
                sum++;
```

First, analyze the if statement. Consider only the  $j$  loop (deal with the  $i$

loop later). The "if" is executed  $i^2$  times or at most  $n^2$  times. But, it is only true  $O(n)$  times because it is true exactly  $i$  times. Thus the innermost loop, the  $k$  loop, is only executed  $O(n)$  times. The  $k$  loop still goes up to  $j$  which is at most  $n^2$ .

If this is hard to see, try it with numbers. If  $n$  (worse case for  $i$ ) is 10, then  $n^2$  (worse case for  $j$ ) is 100. So  $j$  is 100 when  $i$  is 10. Consider when  $j \% 10$  is true (as  $j$  runs through the ints up through 100) . It's true 10 times ( $n$  times) (when  $j$  is 10, 20, 30, ..., 100).

$$\sum_{i=1}^n \sum_{k=1}^{j=O(n^2)} 1 = \sum_{i=1}^n (i * n^2) = n^2 * \sum_{i=1}^n i = n^2 * \frac{n(n+1)}{2}$$

$$\text{So, } T(n) = O( n^2 * (1/2 n^2 + 1/2 n) ) = O( 1/2 n^4 + 1/2 n^3 ) = O(n^4)$$
